You must make a Python problem that can solve the Shakespearean Monkey problem.

- Initialize a population of string.
- Make a fitness function that gives a value for a string. How close is it to the solution.
- Assert fitness for all strings in your population. Let the best 10 percent of the population go straight to the next population. Fill the remaining 90% of the population with crossover and mutations of the best ones.
- Start all over with assigning fitness to strings, and so forth. Repeat until you reach the string “To be or not to be..”
