ERHVERVS AKADEMI AARHUS

ML Exercises, day 7.

Exercises:

Exercise Comedians – Decision Tree.

In groups of 2-3.

We are now going to decide whether to see a standup show or not.

In the example, a person will try to decide if he/she should go to a comedy show or not.

Luckily our example person has registered every time there was a comedy show in town, and registered some information about the comedian, and also registered if he/she went or not.

With that information, we can now make a decision tree.

Where: The decision tree uses your earlier decisions to calculate the odds for you to wanting to go see a comedian or not.

Look in the code Comedians.py

Make changes to the code that allow you to see different sizes/depths of decisions tree.
In the group interpret what the decision tree shows you.

Next:

We can use the Decision Tree to predict new values.

Example: Should I go see a show starring a 40 years old American comedian, with 10 years of experience, and a comedy ranking of 7?

(see the code).

Then:
What would the answer be if the comedy rank was 6?

This decision tree example is explained in further detail on
